## **Robust Estimation : RANSAC**

# RECALL: Parameter Estimation:

Let's say we have found point matches between two images, and we think they are related by some parametric transformation (e.g. translation; scaled Euclidean; affine). How do we estimate the parameters of that transformation?

## General Strategy

- Least-Squares estimation from point correspondences

But there are problems with that approach....

# Problem : Outliers

Loosely speaking, outliers are points that don't "fit" the model.

# Bad Data => Outliers

Loosely speaking, outliers are points that don't "fit" the model.  
Points that do fit are called "inliers"

# Problem with Outliers

Least squares estimation is sensitive to outliers,  
so that a few outliers can greatly skew the result.

Least squares  
regression with  
outliers

compare

**Solution: Estimation methods  
that are robust to outliers.**

# Outliers aren't the Only Problem

**Multiple structures can also skew the results. (the fit procedure implicitly assumes there is only one instance of the model in the data).**

# Robust Estimation

- View estimation as a two-stage process:
  - Classify data points as outliers or inliers
  - Fit model to inliers while ignoring outliers
- Example technique: RANSAC  
(**RAN**dom **SA**mples **C**onsensus)

M. A. Fischler and R. C. Bolles (June 1981). "Random Sample Consensus: A Paradigm for Model Fitting with Applications to Image Analysis and Automated Cartography". *Comm. of the ACM* **24**: 381--395.

### Algorithm 15.4: RANSAC: fitting lines using random sample consensus

Determine:

- s** — the smallest number of points required
- N** — the number of iterations required
- d** — the threshold used to identify a point that fits well
- T** — the number of nearby points required  
to assert a model fits well

Until **N** iterations have occurred

Draw a sample of **s** points from the data  
uniformly and at random

Fit to that set of **s** points

For each data point outside the sample

Test the distance from the point to the line

against **d** if the distance from the point to the line  
is less than **d** the point is close

end

If there are **T** or more points close to the line

then there is a good fit. Refit the line using all  
these points.

end

Use the best fit from this collection, using the  
fitting error as a criterion

(Forsyth & Ponce)

# How Many Samples to Choose?

$e$  = probability that a point is an outlier

$s$  = number of points in a sample

$N$  = number of samples (we want to compute this)

$p$  = desired probability that we get a good sample

**Solve the following for  $N$ :**

$$1 - (1 - (1 - e)^s)^N = p$$

**Where in the world did that come from? ....**

# How Many Samples to Choose?

$e$  = probability that a point is an outlier

$s$  = number of points in a sample

$N$  = number of samples (we want to compute this)

$p$  = desired probability that we get a good sample

$$1 - \underbrace{(1 - (1 - e)^s)}_{}^N = p$$

**Probability that choosing  
one point yields an inlier**

# How Many Samples to Choose?

$e$  = probability that a point is an outlier

$s$  = number of points in a sample

$N$  = number of samples (we want to compute this)

$p$  = desired probability that we get a good sample

$$1 - \underbrace{(1 - (1 - e)^s)}_{\text{Probability of choosing } s \text{ inliers in a row (sample only contains inliers)}}^N = p$$

**Probability of choosing  
 $s$  inliers in a row (sample  
only contains inliers)**

# How Many Samples to Choose?

$e$  = probability that a point is an outlier

$s$  = number of points in a sample

$N$  = number of samples (we want to compute this)

$p$  = desired probability that we get a good sample

$$1 - \underbrace{(1 - (1 - e)^s)}_{\text{Probability that one or more points in the sample were outliers (sample is contaminated)}}^N = p$$

**Probability that one or more  
points in the sample were outliers  
(sample is contaminated).**

# How Many Samples to Choose?

$e$  = probability that a point is an outlier

$s$  = number of points in a sample

$N$  = number of samples (we want to compute this)

$p$  = desired probability that we get a good sample

$$1 - \underbrace{(1 - (1 - e)^s)}_{\text{Probability that } N \text{ samples were contaminated.}}^N = p$$

**Probability that  $N$  samples  
were contaminated.**

# How Many Samples to Choose?

$e$  = probability that a point is an outlier

$s$  = number of points in a sample

$N$  = number of samples (we want to compute this)

$p$  = desired probability that we get a good sample

$$\underbrace{1 - (1 - (1 - e)^s)^N}_{\text{Probability that at least one sample was not contaminated}} = p$$

**Probability that at least  
one sample was not  
contaminated  
(at least one sample of  $s$   
points is composed of only  
inliers).**

# How many samples?

Choose  $N$  so that, with probability  $p$ , at least one random sample is free from outliers. e.g.  $p=0.99$

$$(1 - (1 - e)^s)^N = 1 - p$$

$$N = \frac{\log(1 - p)}{\log(1 - (1 - e)^s)}$$

proportion of outliers $e$							
s	5%	10%	20%	25%	30%	40%	50%
2	2	3	5	6	7	11	17
3	3	4	7	9	11	19	35
4	3	5	9	13	17	34	72
5	4	6	12	17	26	57	146
6	4	7	16	24	37	97	293
7	4	8	20	33	54	163	588
8	5	9	26	44	78	272	1177

# Example: **N** for the line-fitting problem

- $n = 12$  points
- Minimal sample size  $s = 2$
- 2 outliers:  $e = 1/6 \Rightarrow 20\%$
- So  $N = 5$  gives us a 99% chance of getting a pure-inlier sample
  - Compared to  $N = 66$  by trying every pair of points

$$66 = (12 * 11) / 2 \text{ (Brute Force)}$$

# Acceptable consensus set?

- We have seen that we don't have to exhaustively sample subsets of points, we just need to randomly sample  $N$  subsets.
- However, typically, we don't even have to sample  $N$  sets!
- Early termination: terminate when inlier ratio reaches expected ratio of inliers

$$T = (1 - e) * (\text{total number of data points})$$

# RANSAC: Picking Distance Threshold $d$

- Usually chosen empirically
- But...when measurement error is known to be Gaussian with mean 0 and variance  $\mathbf{S}^2$ :
  - Sum of squared errors follows a  $\chi^2$  distribution with  $\mathbf{m}$  DOF, where  $\mathbf{m}$  is the DOF of the error measure (the *codimension*)
  - (*dimension + codimension*) = *dimension of parameter space*
    - E.g.,  $\mathbf{m} = 1$  for line fitting because error is perpendicular distance
    - E.g.,  $\mathbf{m} = 2$  for point distance
- Examples for probability  $\mathbf{p} = 0.95$  that point is inlier

$\mathbf{m}$	Model	$d^2$
1	Line, fundamental matrix	$3.84 \mathbf{S}^2$
2	Homography, camera matrix	$5.99 \mathbf{S}^2$

# After RANSAC

- RANSAC divides data into inliers and outliers and yields estimate computed from minimal set of inliers with greatest support
- Improve this initial estimate with Least Squares estimation over all inliers (i.e., standard minimization)
- Find inliers wrt that L.S. line, and compute L.S. one more time.

# Practical Example

- Stabilizing aerial imagery using RANSAC
  - find corners in two images
  - hypothesize matches using NCC
  - do RANSAC to find matches consistent with an affine transformation
  - take the inlier set found and estimate a full projective transformation (homography)

# Stabilization Application

**Input:** two images from an aerial video sequence.

Note that the motion of the camera is “disturbing”

# Stabilization Application

Step1: extract Harris corners from both frames. We use a small threshold for R because we want LOTS of corners (fodder for our next step, which is matching).

Harris corners for first frame

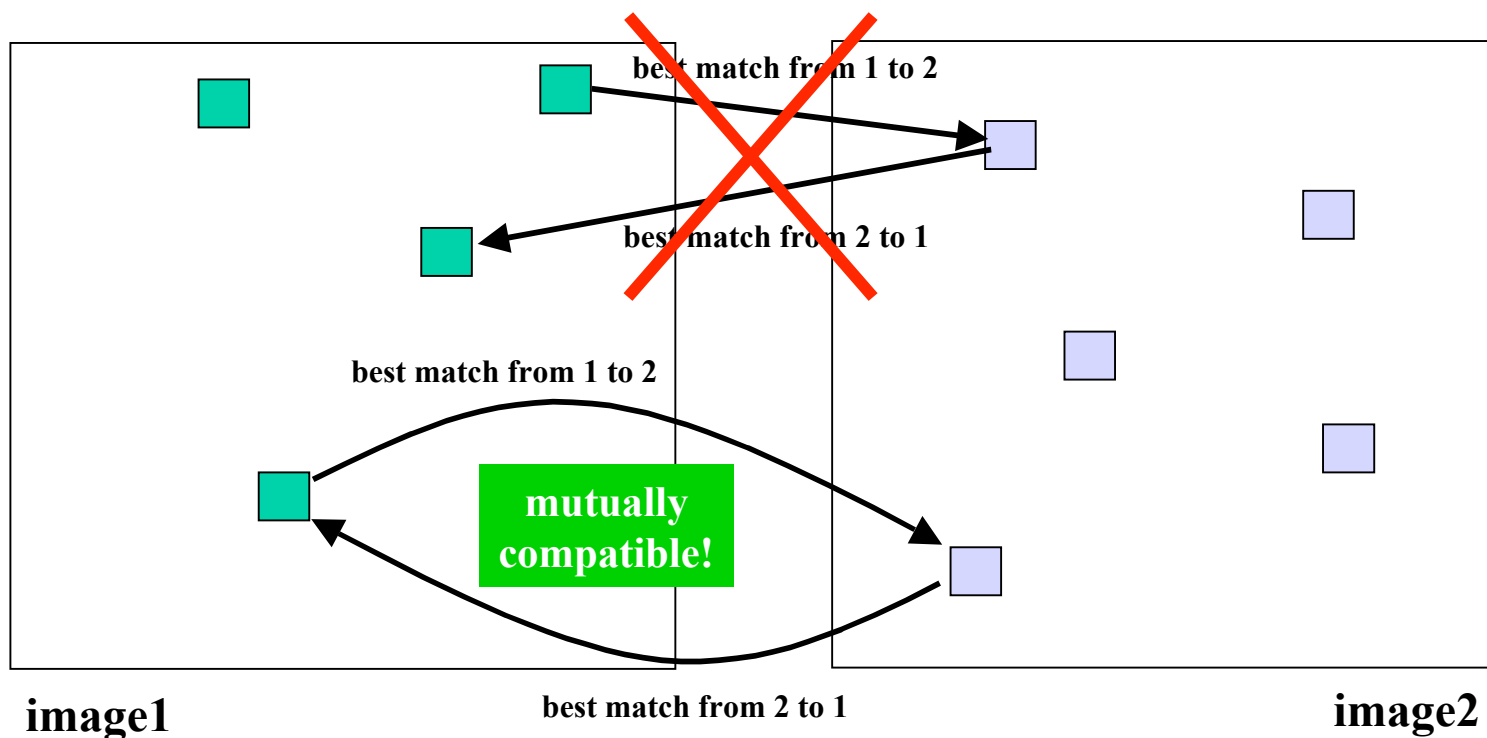

Detailed view

# Stabilization Application

Step2: hypothesize matches. For each corner in image 1, look for matching intensity patch in image2 using NCC. Make sure matching pairs have highest NCC match scores in BOTH directions.

# Stabilization Application

Step2: hypothesize matches.

**yikes!**

As you can see, a lot of false matches get hypothesized. The job of RANSAC will be to clean this mess up.

# Stabilization Application

Step3: Use RANSAC to robustly fit best affine transformation to the set of point matches.

$$\begin{aligned}x_i' &= a x_i + c y_i + c \\y_i' &= d x_i + e y_i + f\end{aligned}$$

**How many unknowns?**

**How many point matches are needed?**

# Stabilization Application

Step3: Use RANSAC to robustly fit best affine transformation to the set of point matches.

Affine transformation has 6 degrees of freedom.

We therefore need 3 point matches [each gives 2 equations]

Randomly sample sets of 3 point matches. For each, compute the unique affine transformation they define. How?

# Stabilization Application

How to compute affine transformation from 3 point matches?  
Use Least Squares! (renewed life for a nonrobust approach)

$$\begin{bmatrix} \sum x_i^2 & \sum x_i y_i & \sum x_i & 0 & 0 & 0 \\ \sum x_i y_i & \sum y_i^2 & \sum y_i & 0 & 0 & 0 \\ \sum x_i & \sum y_i & \sum 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \sum x_i^2 & \sum x_i y_i & \sum x_i \\ 0 & 0 & 0 & \sum x_i y_i & \sum y_i^2 & \sum y_i \\ 0 & 0 & 0 & \sum x_i & \sum y_i & \sum 1 \end{bmatrix} \begin{bmatrix} a \\ b \\ c \\ d \\ e \\ f \end{bmatrix} = \begin{bmatrix} \sum x_i x_i' \\ \sum y_i x_i' \\ \sum x_i' \\ \sum x_i y_i' \\ \sum y_i y_i' \\ \sum y_i' \end{bmatrix}$$

Then transform all points from image1 to image2 using that computed transformation, and see how many other matches confirm the hypothesis.

Repeat N times.

# Stabilization Application

**original point matches**

**labels from RANSAC**

**green: inliers**

**red: outliers**

# Stabilization Example

Step4: Take inlier set labeled by RANSAC, and now use least squares to estimate a projective transformation that aligns the images. (we will discuss this ad nauseum in a later lecture).

Projective Transformation

# Stabilization Example

Step4: estimate projective transformation that aligns the images.

Now it is easier for people (and computers) to see the moving objects.
